Field of study: Applied Mathematics

Specialty: Computational Mathematics

**Master Thesis**

**APPLICATIONS OF WAVELETS IN DATA  
MINING**

Kinga Kurowska

keywords:

wavelets

statistics

learning and adaptive systems

Short summary:

*\*\* To be changed \*\**

The aim of this thesis is an analysis and comparison of statistical methods employing wavelets. Special attention will be paid to data mining and machine learning methods.

# Introduction

*\*\* Few words about my thesis... Generally what is a data mining, what are the wavelets, what are the applications in data mining and finally, what is the main purpose - edge detection. \*\**

## Chapter 1

# Wavelets theory

What exactly is a wavelet? A wavelet means a small wave. This term says a lot about its nature. Wavelets are a family of functions which oscillate like a wave and should be compactly supported. Additionally, the wavelet has zero mean.

**Definition 1.1.** Wavelets are created by scaling and shifting of the, so called, mother wavelet  $\psi(t)$ . The child wavelets are defined as

$$\psi^{(a,b)}(t) = |a|^{-\frac{1}{2}} \psi\left(\frac{t-b}{a}\right), \quad a > 0. \quad (1.1)$$

There are plenty of different mother wavelets, for example

Figure 1.1: Different types of wavelets.

*\*\* Add more about wavelets properties? \*\**

### 1.1. Daubechies wavelets

Each type of wavelet function is more suitable for different applications. The best for image analysis are the Daubechies wavelets.

**Definition 1.2.** Daubechies wavelets are collection of orthogonal and compactly supported functions. A denotation for those wavelets is  $dbN$ , where  $N$  means a maximal number of vanishing moments.

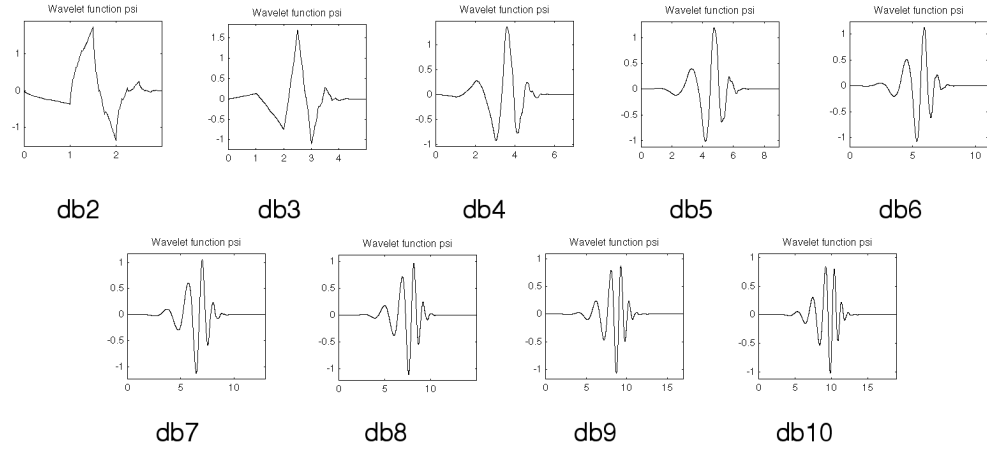

Figure 1.2: Daubechies wavelets.

## 1.2. Wavelet Transform

*\*\* Add some short introduction? \*\**

**Definition 1.3.** Wavelet transform

$$W(a, b) = \int_{-\infty}^{\infty} y(t) a^{-\frac{1}{2}} \psi\left(\frac{t-b}{a}\right) dt, \quad (1.2)$$

where  $a$  is scale parameter,  $b$  translation parameter and  $y(t)$  original signal.

### 1.2.1. Wavelet transform vs Fourier transform

**Definition 1.4.** Fourier transform

$$Y(f) = \int_{-\infty}^{\infty} y(t) e^{-i\omega t} dt, \quad (1.3)$$

where  $y(t)$  is time domain signal and  $Y(f)$  is frequency domain signal.

Wavelet transform	Fourier transform
Suitable for stationary and non-stationary signals	Suitable for stationary signals
High time and frequency resolution	Zero time resolution and very high frequency resolution
Very suitable for studying the local behaviours of the signal	No suitable
Sine and cosine waves	Scaled and translated mother wavelets

Table 1.1: Differences between Wavelet Transform and Fourier Transform.

What differs both transformations is the type of function. In Fourier case there are sine and cosine functions, wherein wavelet transform uses wavelets. Why use the Wavelet transform? Sine function oscillates on the whole real axis, thus it cannot represent abrupt changes. However, the Wavelet transform is localized in space and time, so it can be used to detect sudden changes in signals and images. Moreover, wide range of wavelet functions is a main advantage of wavelet analysis.

### 1.3. Discrete Wavelet transform

There are two types of the wavelet transform:

- Continuous Wavelet Transform (CWT),
- Discrete Wavelet Transform (DWT).

DWT is used to denoising and compression of signals and images. Also, DWT allows to detect smooth regions interrupted by edges or abrupt changes in contrast of images.

Scale and translation parameters are defined as

$$a = 2^j \text{ and } b = 2^j k, \quad j, k = 1, 2, \dots \quad (1.4)$$

to avoid redundancy in coefficients.

The figure 1.3 on a page 9 shows how DWT works. Discrete Wavelet Transform splits signal with two filters:  $g(n)$  - low pass filter (LPF) and  $h(n)$  - high pass filter (HPF). The LPF captures a part with lower frequencies which is the main signal. Whereas, the HPF captures higher frequencies - a noise of the signal. Subsequently, both parts are downsampled by a factor of 2. This decomposition can be repeated on the LPF part of the signal. Hence, the next levels of DWT coefficients.

Figure 1.3: Discrete Wavelet transform on a signal  $x(n)$ .

### 1.4. 2-D Discrete Wavelet transform

2-Dimensional Discrete Wavelet Transform works similar way as 1-D with High Pass Filter, Low Pass Filter and downsampling, except that one level of the decomposition includes double filtering, on columns and rows. The figure 1.4 shows an image decomposition. Firstly, the DWT is applied on columns

of the input image and then on the rows of the both outputs. Ultimately, there are four results:

- LL - result of LPF applied on both, columns and rows,
- LH - result of LPF applied on columns and HPF on rows,
- HL - result of HPF applied on columns and LPF on rows,
- HH - result of HPF applied on both, columns and rows.

Figure 1.4: 2-D Discrete Wavelet transform on an image.

Recall that the outcome of Low Pass Filter in the previous case was the main signal (without a noise). Thus, a 2-Dimensional equivalent is an approximation of an analysed image. The High Pass Filter captures high frequencies, then for an image the outcome are sudden changes in the image contrast. Now, let's focus on what exactly each result represents. First one, the LL is just an approximation of the initial image. Next, the LH shows abrupt changes in a horizontal direction, whereas the HL part presents similar issues but in a vertical direction. The HH shows sudden changes in a diagonal direction. In conclusion, the output of 2-D DWT gives us an approximation of the image and three parts with abrupt changes in different directions. What information gives us these sudden variations? Thanks to those we are able to find places where two smooth regions meet. This kind of image anomaly could be interpreted as edges.

## Chapter 2

# Edge detection

In this chapter let us focus on the main goal of the thesis, which is edge detection. What is an edge? It is a place where image brightness changes rapidly. There are various methods to identify such discontinuities. The most popular are gradient based (e.g. Canny, Prewitt, Sobel) and Laplacian based. However, there is also another method, which provides similar results and can be more efficient in terms of computation. This method is based on the 2-Dimensional Discrete Wavelet Transform described in section 1.4.

What should be done? *\*\* Link to article Edge detection \*\**

1. Convert image to grey scale.
2. Apply 2-D DWT on an image.
3. Remove the LL part.
4. Denoise the LH, HL and HH coefficients.
5. Reconstruct the initial image.
6. Post-processing - modify contrast to emphasize obtained edges.

## 2.1. Implementation of an algorithm

The algorithm is implemented in **Python** using library/package (?) **PyWavelets**. There are used also auxiliary libraries like: **numpy**, **matplotlib**, **PIL** and **scipy**. The **PyWavelets** package contains all features required to edge detection algorithm, i.e. 2D Forward and Inverse Discrete Wavelet Transform, build-in many wavelet functions and thresholding functionality (used to denoise coefficients).

Initially, a colour image must be simplified by conversion to grey scale. Edges are recognised as changes in brightness, so a single pixel should contains only information about a colour (black) intensity. Then we can apply the 2D DWT function. As a result, according to the description in section 1.4, we obtain four components: LL, LH, HL and HH. The last three contains information about rapid brightness changes. Thus, we can remove the LL component. Subsequently, remaining components can be denoised. It means, we can /pozbyc sie/ small coefficients by thresholding. There are two types of thresholding hard and soft. The hard one /nadaje/ zero value for coefficients below the set threshold, while the soft one works in the same way on the coefficients smaller than threshold, but additionally the coefficient bigger than the set threshold are "shrunked" towards zero /o jego wartosc/. More about setting the threshold is described in section 2.2. We used the soft thresholding because then obtained edges are smoother.

The last main step in the algorithm is the reconstruction of the initial image, i.e. application an inverse 2-D DWT on the denoised coefficients. In the result, we obtain the edges of the image. At the end, we can do some post-processing to emphasize obtained lines. The background has grey colour and the edges are more white or black. Therefore, using simple mathematical calculations we can modify image to have black background and white edges. It is enough to get an absolute value, subtract 128 and then scale by multiplying 2 times. *\*\* Add some more about values in an image array, here or in the previous paragraph \*\**

## 2.2. Thresholding

As it was mentioned before there is hard and soft thresholding. Lets denote  $\lambda$  as threshold and  $d$  as wavelet coefficient. The thresholdings are defined respectively

$$D^H(d|\lambda) = \begin{cases} 0, & \text{for } |d| \leq \lambda, \\ d, & \text{for } |d| > \lambda. \end{cases} \quad (2.1)$$

$$D^S(d|\lambda) = \begin{cases} 0, & \text{for } |d| \leq \lambda, \\ d - \lambda, & \text{for } d > \lambda, \\ d + \lambda, & \text{for } d < -\lambda. \end{cases} \quad (2.2)$$

The key is how to set the  $\lambda$  to denoise coefficients and do not loose any significant information. *\*\* Some more about it and how I choose the threshold \*\**

## 2.3. Example

*\*\* Show how algorithm work on a simple square \*\**
